

Predicting flower colour from environment (n = 1,438 species, 417 genera)

Colour–environment associations are statistically robust but weakly predictive: the best environment model reaches balanced accuracy 0.363 against a 0.333 chance floor. Knowing a species' genus lifts macro-F₁ 2.7× further above the majority floor than its entire climate and soil niche, and PC2 is the only informative axis — independently reproducing the MCMCglmm result.
